Enhanced performance, evaluation, and interpretation of the various forms of cardi ological diagnostic procedures and open-heart surgery, the achievement of a rapid improvement in the oxygen consumption of hypoxic myocardium, and the salvage of viable but ischemic myocardium still appear to constitute the most important chal lenges to modern medicine. Research on the vascular anatomy of the myocardium has mostly been focused on the coronary arteries and myocardial capillaries (von Lüdinghausen 2002); by comparison, the coronary or cardiac venous systems have traditionally been neglected. A search through the literature of the mid-twentieth century onwards fails to reveal a detailed report on the anatomy and topography of the coronary sinus (CS) and its related veins (Smith 1962). In this area, new frontiers have been crossed through the use of the technique of CS catheterization, for instance for the purpose of: 1. The visualization of the venous part of cardiac circulation [angiography, computed tomography (CT) I. Methods of visualization of the coronary venous drainage system using electron-beam CT and angiographical methods have recently been presented by Schaffler et al. (2000) and Sun et al. (2002). 2. Electro-physiological study of the atrial components of the conduction system. The morphology of accessory pathways of the conduction system in the neighborhood of the CS, their diagnostics and surgical treatment have been investigated and discussed by Becker et al. (1978), Seally and Mikat (1983), Robinson et al. (1988), and Sun et al. (2002).
